Multilabel classification

- Multilabel classification is an important research field in machine learning.
  - For example, a document can be classified as "science", "genomics", and "drug discovery".
  - Each input variable $\mathbf{x} \in \boldsymbol{\mathcal{X}}$ is associated with multiple output variables $\mathbf{y} \in \boldsymbol{\mathcal{Y}}, \boldsymbol{\mathcal{Y}} = \mathcal{Y}_1 \times \cdots \times \mathcal{Y}_l, \mathcal{Y}_i = \{+1, -1\}$.
  - The goal is to find a mapping function that predicts the best values of an output given an input $f \in \mathcal{H} : \boldsymbol{\mathcal{X}} \rightarrow \boldsymbol{\mathcal{Y}}$.
- The central problems of multilabel classification:
  - The size of the output space $\boldsymbol{\mathcal{Y}}$ is exponential in the number of microlabels.
  - The dependency of microlabels needs to be exploited to improve the prediction performance.

Structured output learning

- There is an *output graph* connecting multiple labels.
  - A set of nodes represents multiple labels.
  - A set of edges represents the correlation between labels.
- Hierarchical classification:
  - The output graph is a rooted tree or a directed graph defining different levels of granularities.
  - For example, SSVM, ...
- Graph labeling:
  - The output graph often takes a general form (e.g., a tree, a chain).
  - For example, $\mathrm{M^3N}$, CRF, MMCRF, ...
- The output graph is assumed to be known *apriori*.

Research question

- The output graph is hidden in many applications.
  - For example, a surveillance photo can be tagged with "building", "road", "pedestrian", and "vehicle".
- We study the problem in structured output learning when the output graph is not observed.
- In particular:
  - Assume the dependency can be expressed by a complete set of pairwise correlations.
  - Build a structured output learning model with a complete graph as the output graph.
  - Solve the optimization problem and the inference problem ($\mathcal{NP}$-hard).

In this presentation

- A structured prediction model which performs max-margin learning on a random sample of spanning tree.
- Two ways to combine the set of random spanning trees.
  - conical combination
  - convex combination
- The corresponding optimization problem.

Model

- Training examples comes in pair $S = \{(\mathbf{x}_i, \mathbf{y}_i)\}_{i=1}^{m} \in \boldsymbol{\mathcal{X}} \times \boldsymbol{\mathcal{Y}}$.
- A complete graph $G = (E, V)$ is used as the output graph.
- $\Gamma_G(\mathbf{y}_i)$ is the output feature map of $\mathbf{y}_i$ on G

$$\Gamma_G(\mathbf{y}_i) = \{\Gamma_e(\mathbf{y}_{i,e})\}_{e \in G},$$
$$\Gamma_e(\mathbf{y}_{i,e}) = [\mathbf{1}_{\mathbf{y}_{i,e}==00}, \mathbf{1}_{\mathbf{y}_{i,e}==01}, \mathbf{1}_{\mathbf{y}_{i,e}==10}, \mathbf{1}_{\mathbf{y}_{i,e}==11}]$$

- A joint feature map of $(\mathbf{x}_i, \mathbf{y}_i)$

$$\phi_G(\mathbf{x}_i, \mathbf{y}_i) = \varphi(\mathbf{x}_i) \otimes \Gamma_G(\mathbf{y}_i) = \{\phi_e(x_i, \mathbf{y}_{i,e})\}_{e \in G}.$$

- A compatibility score is defined as

$$F(\mathbf{x}, \mathbf{y}; \mathbf{w}_G) = \langle \mathbf{w}_G, \phi_G(\mathbf{x}, \mathbf{y}) \rangle = \sum_{e \in G} \langle \mathbf{w}_{G,e}, \phi_e(\mathbf{x}, \mathbf{y}_e) \rangle$$

- $\mathbf{w}$ ensures an input $\mathbf{x}_i$ with a correct multilabel $\mathbf{y}_i$ achieves a higher score than with any incorrect multilabel $\mathbf{y} \in \mathcal{Y}$.

Model (cont.)

- The predicted output $\mathbf{y}(\mathbf{x})$ for a given input $\mathbf{x}$ is computed by

$$\mathbf{y}(\mathbf{x}) = \operatorname*{\mathbf{argmax}}_{\mathbf{y} \in \boldsymbol{\mathcal{Y}}} F(\mathbf{x}, \mathbf{y}; \mathbf{w}_G) = \operatorname*{\mathbf{argmax}}_{\mathbf{y} \in \boldsymbol{\mathcal{Y}}} \langle \mathbf{w}_G, \phi_G(\mathbf{x}, \mathbf{y}) \rangle,$$

  which is called *inference problem*.

- The inference problem is $\mathcal{NP}$-hard for most joint feature maps on the complete graph.

How to learn w on a complete graph?

- The *margin* of an example $\mathbf{x}_i$ is

$$\gamma_G(\mathbf{x}_i; \mathbf{w}_G) = F(\mathbf{x}_i, \mathbf{y}_i; \mathbf{w}_G) - \max_{\mathbf{y} \in \mathcal{Y}/\mathbf{y}_i} F(\mathbf{x}_i, \mathbf{y}; \mathbf{w}_G).$$

- $\mathbf{w}$ is solved by *maximum-margin principle* which aims to maximize $\gamma(\mathbf{x}_i; \mathbf{w}_G)$ over all training example.
- The problems are:
  - The $\mathcal{NP}$-hardness of the inference problem on a complete graph.
  - A large parameter space: $\Theta(k^2)$
- We aim to use a joint feature map that allows the inference problem be solved in polynomial time.

Superposition of random trees

- $S(G)$ is a complete set of spanning tree generate from G.
- $\mathbf{w}_T = \{\mathbf{w}_{G,e}\}_{e \in T}$ is the projection of $\mathbf{w}_G$ on T.
- $\phi_T(\mathbf{x}, \mathbf{y}) = \{\phi_e(\mathbf{x}, \mathbf{y})\}_{e \in T}$ is the projection of $\phi_G(\mathbf{x}, \mathbf{y})$ on T.
- Rewrite

$$
\begin{aligned}
F(\mathbf{x}, \mathbf{y}, \mathbf{w}_G) &= \sum_{e \in G} \langle \mathbf{w}_{G,e}, \phi_{G,e}(\mathbf{x}, \mathbf{y}_e) \rangle \\
&= \frac{1}{\ell^{\ell-2}} \sum_{T \in S(G)} \sqrt{\frac{\ell}{2}} \langle \mathbf{w}_T, \phi_T(\mathbf{x}, \mathbf{y}_e) \rangle \\
&= \frac{1}{n} \sum_{i=1}^{n} a_{T_i} \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}_e) \rangle,
\end{aligned}
$$

$$
\frac{1}{n} \sum_{i=1}^{n} a_{T_i}^2 = 1, \ \frac{1}{n} \sum_{i=1}^{n} a_{T_i} \leq 1, \ a_{T_i} \geq 0, \ n = \ell^{\ell-2}.
$$

How many trees?

- If there is a predictor $\mathbf{w}_G$ on complete graph achieves a margin on some training data, with high probability we need n spanning tree predictors $\{\mathbf{w}_{T_i}\}_{i=1}^n$ to achieve a close margin. n is quadratic in terms of ℓ.
- Recall

$$F(\mathbf{x}, \mathbf{y}, \mathbf{w}_{\mathcal{T}}) = \frac{1}{n} \sum_{i=1}^{n} a_{T_i} \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}_e) \rangle,$$

$$\frac{1}{n} \sum_{i=1}^{n} a_{T_i}^2 = 1, \ \frac{1}{n} \sum_{i=1}^{n} a_{T_i} \leq 1, \ a_{T_i} \geq 0, \ \cancel{n = \ell^{\ell-2}}.$$

Conical combination

- A sample $\mathcal{T}$ of n spanning trees drawn from G.
- Normalized feature weights $\hat{\mathbf{w}}_{T_i} = \frac{\mathbf{w}_{T_i}}{||\mathbf{w}_{T_i}||}$, $T_i \in \mathcal{T}$.
- Normalized feature vectors $\hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}) = \frac{\phi_{T_i}(\mathbf{x},\mathbf{y})}{||\phi_{T_i}(\mathbf{x},\mathbf{y})||}$, $T_i \in \mathcal{T}$.
- Conical combination of spanning trees

$$F(\mathbf{x}, \mathbf{y}, \mathbf{w}_{\mathcal{T}}) = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}) \rangle$$

$$\sum_{i=1}^{n} q_i^2 = 1, \; q_i \geq 0, \; \forall i \in \{1, \cdots, n\}.$$

Conical combination (cont.)

- To solve $\{\mathbf{w}_{T_i}\}_{T_i \in \mathcal{T}}$, we need to work on the optimization problem

$$\min_{\xi,\gamma,\mathbf{q},\mathcal{W}} \quad \frac{1}{2\gamma^2} + \frac{C}{\gamma}\sum_{k=1}^{m}\xi_k$$

$$\text{s.t.} \quad \frac{1}{\sqrt{n}}\sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}_k, \mathbf{y}_k)\rangle - \max_{\mathbf{y}\in\mathcal{Y}} \frac{1}{\sqrt{n}}\sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}_k, \mathbf{y})\rangle$$

$$\geq \gamma - \xi_k, \xi_k \geq 0, \forall k \in \{1, \cdots, m\}, \sum_{i=1}^{n} q_i^2 = 1, q_i \geq 0, \forall i \in \{1, \cdots, n\}.$$

- This is equivalent to

$$\min_{\mathbf{w}_{T_i},\xi_i} \quad \frac{1}{2}\sum_{i=1}^{n} ||\mathbf{w}_{T_i}||^2 + C\sum_{k=1}^{m}\xi_k$$

$$\text{s.t.} \quad \frac{1}{\sqrt{n}}\sum_{i=1}^{n} \langle \mathbf{w}_{T_i}, \boldsymbol{\phi}_{T_t}(\mathbf{x}_k, \mathbf{y}_k)\rangle - \max_{\mathbf{y}\neq\mathbf{y}_k} \frac{1}{\sqrt{n}}\sum_{i=1}^{n} \langle \mathbf{w}_{T_t}, \boldsymbol{\phi}_{T_i}(\mathbf{x}_k, \mathbf{y})\rangle \geq 1 - \xi_k,$$

$$\xi_k \geq 0\,, \forall\ k \in \{1, \ldots, m\}.$$

Convex combination

- A sample $\mathcal{T}$ of n spanning trees drawn from G.
- Normalized feature weights $\hat{\mathbf{w}}_{T_i} = \frac{\mathbf{w}_{T_i}}{||\mathbf{w}_{T_i}||}$, $T_i \in \mathcal{T}$.
- Normalized feature vectors $\hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}) = \frac{\phi_{T_i}(\mathbf{x},\mathbf{y})}{||\phi_{T_i}(\mathbf{x},\mathbf{y})||}$, $T_i \in \mathcal{T}$.
- Conical combination of spanning trees

$$F(\mathbf{x}, \mathbf{y}, \mathbf{w}_{\mathcal{T}}) = \frac{1}{n} \sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}, \mathbf{y}) \rangle$$

$$\sum_{i=1}^{n} q_i = 1,\ q_i \geq 0,\ \forall i \in \{1, \cdots, n\}.$$

Convex combination (cont.)

- To solve $\{\mathbf{w}_{T_i}\}_{T_i \in \mathcal{T}}$, we need to work on the optimization problem

$$\min_{\xi,\gamma,\mathbf{q},\mathcal{W}} \quad \frac{1}{2\gamma^2} + \frac{C}{\gamma}\sum_{k=1}^{m}\xi_k$$

$$\text{s.t.} \quad \frac{1}{n}\sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}_k, \mathbf{y}_k)\rangle - \max_{\mathbf{y}\in\mathcal{Y}} \frac{1}{n}\sum_{i=1}^{n} q_i \langle \hat{\mathbf{w}}_{T_i}, \hat{\phi}_{T_i}(\mathbf{x}_k, \mathbf{y})\rangle$$

$$\geq \gamma - \xi_k, \xi_k \geq 0, \forall k \in \{1, \cdots, m\}, \sum_{i=1}^{n} q_i = 1, q_i \geq 0, \forall i \in \{1, \cdots, n\}.$$

- This is equivalent to

$$\min_{\mathbf{w}_{T_i},\xi_i} \quad \frac{1}{2}\left(\sum_{i=1}^{n} ||\mathbf{w}_{T_i}||\right)^2 + C\sum_{k=1}^{m}\xi_k$$

$$\text{s.t.} \quad \frac{1}{n}\sum_{i=1}^{n}\langle \mathbf{w}_{T_i}, \phi_{T_t}(\mathbf{x}_k, \mathbf{y}_k)\rangle - \max_{\mathbf{y}\neq\mathbf{y}_k} \frac{1}{n}\sum_{i=1}^{n}\langle \mathbf{w}_{T_t}, \phi_{T_i}(\mathbf{x}_k, \mathbf{y})\rangle \geq 1 - \xi_k,$$

$$\xi_k \geq 0, \ \forall k \in \{1, \ldots, m\}.$$

Convex combination (cont.)

- This can be expressed equivalently as

$$\min_{\mathbf{w}_{T_i},\xi_i,\lambda_i} \quad \frac{1}{2}\sum_{i=1}^{n}\frac{1}{\lambda_i}\left|\left|\mathbf{w}_{T_i}\right|\right|^2 + C\sum_{k=1}^{m}\xi_k$$

$$\textbf{s.t.} \quad \frac{1}{n}\sum_{i=1}^{n}\left\langle \mathbf{w}_{T_i}, \boldsymbol{\phi}_{T_t}(\mathbf{x}_k,\mathbf{y}_k)\right\rangle - \max_{\mathbf{y}\neq\mathbf{y}_k}\frac{1}{n}\sum_{i=1}^{n}\left\langle \mathbf{w}_{T_t}, \boldsymbol{\phi}_{T_i}(\mathbf{x}_k,\mathbf{y})\right\rangle \geq 1-\xi_k,$$

$$\xi_k \geq 0,\ \forall k \in \{1,\ldots,m\},\ \sum_{i=1}^{n}\lambda_i = 1,\ \lambda_i \geq 0,\ \forall i \in \{1,\cdots,n\}.$$

Conclusions

- Theoretical study shows if a large margin structured output learner exists, then the combination of a random sample of spanning trees will achieve a similar margin with a high probability.
- The K-best inference algorithm is tractable which is proved theoretically and empirically.
- RTA is not constrained by the availability of the output graph, it can therefore be applied to a wider range of multilabel classification problem where the output graph is believed to play an important role during learning.
